VERAN - Tool Architecture

A local conversation tool for client advisors.

Input: the advisor chooses a scenario and enters client information, recent chat and relevant product or event facts.

Prompt: the Python backend combines the shared brand rules, one scenario module and the supplied facts. It calls the authenticated Codex CLI to generate a structured response.

Output: the program checks the JSON structure, status, candidate count and Chinese text. When ready, the web page shows three drafts and a separate advisor note. Blocked or information-needed responses show a note instead.

The advisor reviews the drafts and chooses a reply. The tool does not send messages to WeChat. Inputs, prompts, outputs and run metadata are saved locally for review.
